

Abstract

Large companies receive vast amounts of applications for open positions daily, the consequence of which is a dilemma for HR; either reject all but the strongest of CVs, potentially losing out on the ideal candidate, or provide screening interviews for hundreds of applicants, which is resource expensive. This current paradigm is suboptimal for both companies and candidates. The solution? Automate the initial screening interview process using Large Language Models.

This report explores and details the design and development of an LLM-based voice-to-voice screening interview and evaluation system. The report provides useful background information critical to understanding the project, covers the development methodology and implementation of the project, and covers the evaluation of the system's characteristics and performance, finally drawing conclusions on the successes, areas for improvement, and scope of future development.
